Toxicity of a 5-day doxorubicin (Adriamycin) infusion in the dog. This study documents the toxicity of a 5-day continuous intravenous infusion of doxorubicin in dogs. Doxorubicin hydrochloride was

infused at a rate of 0.5 mg/kg/d for 5 days in 10 dogs. A peak plasma concentration of 7.1 +/- 1.0 micrograms/ml was reached on the 4th day of administration. A total dose of 30.2 mg/m² of doxorubicin was delivered over 5 days and the calculated dose intensity was 0.4 mg/kg/d. Doxorubicin was metabolized to doxorubicinol. A decrease in the plasma level of doxorubicinol occurred, presumably due to formation of the doxorubicinol glucuronide. Other metabolites were not detected. Adverse events observed during the infusion period included

hypersalivation, depression, mild paresis, and flaccid paralysis. Lethargy was transiently present during the first 48 hours. Hypoxemia was a consistent finding in dogs with severe cardiopulmonary impairment. The survival rate for all dogs was 75%. There were no dose-related adverse events and no apparent toxicities resulting from a 5-day infusion
