Conventional polymerase chain reaction restriction fragment length polymorphisms for the differentiation of apicomplexan parasites. The circumsporozoite protein (CS) gene of Plasmodium falciparum is one of the most reliable and conserved genetic markers for the molecular typing of this species. We have exploited this particular feature of the CS gene by developing restriction fragment length polymorphism (RFLP) assays for the detection of the species and genotype of Plasmodium parasites infecting humans. DNA was obtained from intra-erythrocytic stages of 19 selected apicomplexan parasites and of three rodent Plasmodium spp. Then, a set of oligonucleotide primers was developed that amplified a portion of the gene containing the conserved motif GAGA. The amplicons were digested with restriction enzymes to generate RFLP patterns allowing species and genotype discrimination. The RFLPs observed for P. falciparum, P. malariae and P. ovale spp. are the same as those obtained for CS gene, whereas for P. vivax, only one subgenus pattern could be recognized. These assays make it possible to characterize accurately the species and genotype of human malaria parasites.Scientists have found a way to make batteries last longer and be cheaper to make. Batteries are generally made of a number of different materials which must be intimately connected in order to work properly. Co-author Simon Archer of the University of Cambridge says that usually this results in a complex structure and hence high manufacturing costs. His and his team's solution is to print batteries into a polymer which can be manufactured cheaply. This also serves to protect the batteries from leaking and to maintain their shape. The team's solution is to print the batteries within a solid polymer which will then behave like a skin for the battery, keeping the positive and negative electrodes from leaking. The battery can then be sandwiched in a thin cellophane membrane. The team demonstrated their technique to replace a lithium-ion battery using a polymer with a variety of different ions to create an electrolyte. The future applications for the technology may be high-powered sensors, electronic circuits, energy-efficient vehicles or regenerative medical devices. "The long-term vision of our research programme is to develop a printable polymer electrolyte material that can be used to replace current lithium-ion batteries in a range
