Continuous therapy is the use of supplemental medication administered continually in an ordered pattern to maintain homeostasis, either as a direct infusion into the patient, or an alternate route such as a transdermal patch, orally administered medication or as a sublingual medication administered under the tongue. The bolus administration of the medication is the traditional clinical practice for using continuous therapy for a majority of patients. However, there are a variety of patients for whom continuous therapy is difficult to administer. For example, adult patients with respiratory problems, and especially those requiring intermittent oxygen therapy, also require continuous therapy for their condition. Also, patients needing blood transfusions, and patients with other medical conditions such as cancer may require continuous therapies. Also, patients on oral medications may benefit from continuous administration of the medication, as continuous administration may prevent the undesirable effects from accumulating in the patient. During continuous therapy, it is highly desirable for the patient to have a high degree of monitoring of the bolus administration of the medication to maintain both the therapeutic effect of the medication and the safety of the patient. This is especially true for patients with respiratory problems. Patient monitoring allows for the actual amount of medication being administered to the patient to be monitored and adjusted. In addition, patient monitoring may be used to determine the actual absorption of the medication, which may affect the effectiveness of the medication in the patient's body. Patient monitoring also allows for administration of medication to be halted when a crisis occurs, which allows the patient to have improved circulation and respiration, and thus aid in the patient's recovery. Therefore, continuous therapy is an extremely useful medical procedure, one that may be life saving for some patients. In order to aid in the monitoring of continuous therapy, it is desirable for a patient to have access to and be able to see a visual display of the amount of medication being administered to the patient. For example, for patients requiring continuous oxygen therapy, it is desirable for the patient to have the ability to view the number of oxygen capsules given to the patient and also to view the amount of oxygen provided by the continuous oxygen administration system. It is also desirable to have an alarm mechanism to alert the patient if oxygen is not being administered, or if the oxygen administration system has malfunctioned. In order to aid in the monitoring of continuous therapy, it is also desirable for a patient to have the ability to self-administer the medication. For example, patients requiring continuous oxygen may also desire to administer their own oxygen from a continuous oxygen supply. This is particularly useful for
