In such an instance, the output of the audio transducer is sampled, in accordance with the Nyquist theorem, at a minimum of twice the maximum frequency in the analog audio signal. Typically, the audio transducer is designed to provide an output with the highest amplitude at a frequency of 20 KHz. The output of the audio transducer is applied to an analog-to-digital converter, which provides a digital output at the highest frequency it can support, which is usually less than 20 KHz. The digital output of the analog-to-digital converter is then applied to a digital decoder, which will then play the compact disc. Although compact discs provide an extremely efficient medium for storing digital information, compact discs are subject to malfunction in the event of damage to the disc, or in the event of failure of the digital decoder. Such problems are not readily apparent when the compact disc is operating normally. Since compact discs are easily accessible, they are the subject of frequent rough handling and accidental breakage. Compact discs have also been subject to intentional damage in order to enhance their sound characteristics. For example, af5dca3d97
